Pulmonary Blood Flow

M1 – Cardiovascular/Respiratory Sequence

Thomas Sisson, MD

Winter, 2009
Objectives

• The student will know the structure, function, distribution and control of pulmonary blood supply
  – Compare pulmonary and bronchial circulation
  – Compare and contrast pulmonary and systemic circulation
  – Describe and explain the effects of cardiac output and lung volume on pulmonary vascular resistance
  – Describe the effects of hypoxia on pulmonary vascular resistance
  – Describe the effects of gravity of pulmonary blood flow
  – Explain Starling’s equation
  – Describe the mechanisms of pulmonary edema
Two Circulations in the Lung

• Pulmonary Circulation.
  – Arises from Right Ventricle.
  – Receives 100% of blood flow.

• Bronchial Circulation.
  – Arises from the aorta.
  – Part of systemic circulation.
  – Receives about 2% of left ventricular output.
Bronchial Circulation
Pulmonary Circulation
Pulmonary Circulation

Patrick J. Lynch, wikimedia commons
Pulmonary Circulation

• In series with the systemic circulation.

• Receives 100% of cardiac output (3.5L/min/m²).

• RBC travels through lung in 4-5 seconds.

• 280 billion capillaries, supplying 300 million alveoli.
  – Surface area for gas exchange = 50 – 100 m²
Alveolar Architecture
Alveolar Airspace
Functional Anatomy of the Pulmonary Circulation

• Thin walled vessels at all levels.

• Pulmonary arteries have far less smooth muscle in the wall than systemic arteries.

• Consequences of this anatomy - the vessels are:
  – Distensible.
  – Compressible.
Pulmonary Circulation Pressures

Pulmonary Vascular Resistance

Vascular Resistance = \( \frac{\text{input pressure} - \text{output pressure}}{\text{blood flow}} \)

\[ PVR = k \cdot \frac{\text{mean PA pressure} - \text{left atrial pressure}}{\text{cardiac output (index)}} \]

mean PA pressure - left atrial pressure = 10 mmHg
mean aorta pressure - right atrial pressure = 98 mmHg

Therefore PVR is 1/10 of SVR
Vascular Resistance is Evenly Distributed in the Pulmonary Circulation
Reasons Why Pressures Are Different in Pulmonary and Systemic Circulations?

- Gravity and Distance:
  - Distance above or below the heart adds to, or subtracts from, both arterial and venous pressure
  - Distance between Apex and Base

</tbody>
</table>
Reasons Why Pressures Are Different in Pulmonary and Systemic Circulations?

• Control of regional perfusion in the systemic circulation:
  – Large pressure head allows alterations in local vascular resistance to redirect blood flow to areas of increased demand (e.g. to muscles during exercise).
  – Pulmonary circulation is all performing the same job, no need to redirect flow (exception occurs during hypoxemia).

• Consequences of pressure differences:
  – Left ventricle work load is much greater than right ventricle
  – Differences in wall thickness indicates differences in work load.
Influences on Pulmonary Vascular Resistance

Pulmonary vessels have:
- Little vascular smooth muscle.
- Low intravascular pressure.
- High *distensibility* and *compressibility*.

Vessel diameter influenced by extravascular forces:
- Gravity
- Body position
- Lung volume
- Alveolar pressures/intrapleural pressures
- Intravascular pressures
Influences of Pulmonary Vascular Resistance

• Transmural pressure = Pressure Inside – Pressure Outside.
  – Increased transmural pressure-increases vessel diameter.
  – Decreased transmural pressure-decreased vessel diameter (increase in PVR).
  – Negative transmural pressure-vessel collapse.

• Different effects of lung volume on alveolar and extraalveolar vessels.
Effect of Transmural Pressure on Pulmonary Vessels During Inspiration

Resistance \(\propto\) Length and Resistance \(\propto\) \(1/(\text{Radius})^4\)

Effect of Lung Volume on PVR

Pulmonary Vascular Resistance During Exercise

• During exercise cardiac output increases (e.g. 5-fold), but with little change in mean pulmonary artery pressure
  – How is this possible?

  \[ \Delta \text{Pressure} = \text{Flow} \times \text{Resistance} \]

  \[
  \text{Vascular Resistance} = \frac{\text{input pressure} - \text{output pressure}}{\text{blood flow}}
  \]

• \( \Delta \text{Pressure} = \text{Flow} \times \text{Resistance} \)

• If pressure does not change, then PVR must decrease with increased blood flow
  • Passive effect (seen in isolated lung prep)
    – Recruitment: Opening of previously collapsed capillaries
    – Distensibility: Increase in diameter of open capillaries.
Recruitment and Distention in Response to Increased Pulmonary Artery Pressure

West. Respiratory Physiology: The Essentials 8th ed. Lippincott Williams & Wilkins. 2008
Gravity, Alveolar Pressure and Blood Flow

- Pressure in the pulmonary arterioles depends on both mean pulmonary artery pressure and the vertical position of the vessel in the chest, relative to the heart.

- Driving pressure (gradient) for perfusion is different in the 3 lung zones:
  - Flow in zone 1 may be absent because there is inadequate pressure to overcome alveolar pressure.
  - Flow in zone 3 is continuous and driven by the pressure in the pulmonary arteriole – pulmonary venous pressure.
  - Flow in zone 2 may be pulsatile and driven by the pressure in the pulmonary arteriole – alveolar pressure (collapsing the capillaries).
Gravity, Alveolar Pressure, and Blood Flow

Typically no zone 1 in normal healthy person

Large zone 1 in positive pressure ventilation + PEEP

T. Sisson
Hypoxic Pulmonary Vasoconstriction

- Alveolar hypoxia causes active vasoconstriction at level of pre-capillary arteriole.

- Mechanism is not completely understood:
  - Response occurs locally and does not require innervation.
  - Mediators have not been identified.
  - Graded response between pO2 levels of 100 down to 20 mmHg.

- Functions to reduce the mismatching of ventilation and perfusion.

- Not a strong response due to limited muscle in pulmonary vasculature.

- General hypoxemia (high altitude or hypoventilation) can cause extensive pulmonary artery vasoconstriction.
Barrier Function of Alveolar Wall

• Capillary endothelial cells:
  – permeable to water, small molecules, ions.
  – barrier to proteins.

• Alveolar epithelial cells:
  – more effective barrier than the endothelial cells.
  – recently found to pump both salt and water from the alveolar space.
Alveolar airspace
Fluid Movement Due to Osmotic Pressure

Water moves through the semi-permeable membrane down a concentration gradient to dilute the solute.
Osmotic Pressure Gradient Can Move Fluid Against Hydrostatic Pressure

Before

After

Glass tube

Permeable membrane
Osmotic Gradient Counteracts Hydrostatic Gradient

- Hydrostatic pressure in the pulmonary capillary bed > hydrostatic pressure in the interstitium
  - hydrostatic pressure drives fluid from the capillaries into the pulmonary interstitium

- Osmotic pressure in the plasma > osmotic pressure in the interstitium
  - osmotic pressure normally would draw fluid from the interstitial space into the capillaries
**Starling’s Equation**

\[ Q = K[(P_c - P_i) - \sigma(\pi_c - \pi_i)] \]

- \( Q \) = flux out of the capillary
- \( K \) = filtration coefficient
- \( P_c \) and \( P_i \) = capillary and interstitial hydrostatic pressures
- \( \pi_c \) and \( \pi_i \) = capillary and interstitial osmotic pressures
- \( \sigma \) = reflection (sieving) coefficient
Normally Starling’s Forces Provide Efficient Protection

- Normal fluid flux from the pulmonary capillary bed is approximately 20 ml/hr.
  - recall that cardiac output through the pulmonary capillaries at rest is ~5 l/min.
  - < 0.0066% leak.

- Abnormal increase in fluid flux can result from:
  - Increased hydrostatic pressure gradient (cardiogenic pulmonary edema).
  - Decreased osmotic pressure gradient (cirrhosis, nephrotic syndrome).
  - Increased protein permeability of the capillary wall (ARDS).
